ABSTRACT: P. I. VOYEVODIN died on 25 November 1964; one of the oldest bolshevik-Leninists, he was a member of the CPSU already in 1899. He fought in the early battles of the revolution, was imprisoned and sent to Siberia in 1905. After the October Revolution he became an economic adviser to Lenin on matters pertaining to Siberia and the entire Soviet Union as well. He was active in planning and organizing GOELRO. In 1921 he was assigned to set up the new Russian cinema industry, later he turned to the problems of electrification: spreading Lenin's ideas, publishing books and periodicals on the subject. He was the first Soviet editor of "Elektrichestvo" and then the editor of "Elektrifikatsiya." He partici-

TITLE: Phase transition in  $MnF_2$  at high pressures

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 6, 1965, 1728-1732

TOPIC TAGS: phase transition, metastable phase, x ray analysis, manganese compound, fluoride, crystal lattice structure, pressure effect

ABSTRACT: This is a continuation of earlier work on the same subject, with an aim at determining the conditions under which  $MnF_2$  with an  $\alpha$ - $PbO_2$  structure is formed. To this end, the effect of high pressure on the structure of  $MnF_2$  was measured at pressures up to 80 kbar. Whereas in the earlier investigation the x-ray structure could be determined only after removal of the pressure, the method in the present study made it possible to obtain x-ray patterns directly at high pressures. The method is described elsewhere (S. S. Kabalkina and Z. V. Troitskaya, DAN SSSR v. 151, 1068, 1963). The results show that at pressures  $p > 20$ --30 kbar the initial phase of  $MnF_2$  with rutile structure experiences a reversible phase transition. It is assumed on the basis of the data that the high pressure  $MnF_2$  phase has a distorted structure of the  $CaF_2$  type, which is close to the structure of the tetragonal  $ZrO_2$  modification. After removal of the pressure, a metastable phase with a structure of the  $\alpha$ - $PbO_2$  type

SOURCE: Zh eksper i teor fiz, v. 51, no. 2, 1966, 377-382

TOPIC TAGS: phase transition, high pressure research, high pressure, tellurium dioxide, x ray diffraction

ABSTRACT: The effect of high pressure on the structure of the tetragonal phase of  $\text{TeO}_2$  is investigated. An x-ray diffraction study of the structure of  $\text{TeO}_2$ I at room temperature and under pressures up to 100 kbar was carried out in a special x-ray chamber which included an amorphous boron pellet. The experiments show that at  $p > 30$  kbar,  $\text{TeO}_2$ I undergoes a reversible phase transition of the first kind. According to the data obtained, the high-pressure phase ( $\text{TeO}_2$ II) possesses a rhombic lattice cell with the following parameter values at  $p = 60$  kbar:  $a = 4.22 \text{ \AA}$ ,  $b = 4.84 \text{ \AA}$ ,  $c = 3.67 \text{ \AA}$ ,  $z = 2$ ,  $\rho = 7.07 \text{ g/cm}^3$ ; it belongs to the Fedorov Pnm group. It is suggested that the high-pressure phase

## Strengthening of Large-module Gears by Surface Treatment

e) contour hardening plus shot peening. The gears were tested for: 1) static fatigue (on a hydraulic pulsator with a frequency of 460 load changes per minute, over  $1 \times 10^6$  cycles, with an asymmetrical non-reversing loading of 2 tons per tooth [ $l$  shortened to 15 mm]; 2) impact fatigue (during bend-testing on an N. A. Lopatinskiy machine). In both cases the test ended with the appearance of fatigue cracks at the base of the tooth. Better results were exhibited by gears of steel 12Kh2N4A and 12KhN3A, and gears of similar strength made from steel 50, all treated as per (c) and (d) above -- the (d) treatment being the simpler. Treatments (b) and (e) yielded low cyclic strength values. Gears of the 18KhGT steel were inferior in strength to those of Cr-Ni steels, even after shot peening of the teeth.

TITLE: Strengthening of Large-module Gears by Surface Treatment  
(Uprochneniye krupnomodul'nykh shesteren poverkhnostnoy obrabotkoy)

PERIODICAL: V sb.: Vopr. konstrukts. prochnosti stali. Moscow, Mashgiz, 1957, pp 67-82

ABSTRACT: An investigation was made of the drive gears of the traction motor of an internal-combustion-engine locomotive.  $m$  (the gear module) = 10;  $l$  (the tooth length) = 140 mm;  $T$  (the number of teeth) = 16. The gears were made from steels 12Kh2N4A, 12KhN3A, and 18KhGT and had undergone casehardening, high-temperature tempering, oil quenching, and tempering at 150°C. The gears made from steel 50 were oil-quenched and tempered at 560° and then subjected to one of the following treatments: a) a partial hardening of the working part of the tooth with a high-frequency current; b) contour hardening with a high-frequency current; c) partial hardening with a high-frequency current and by shot peening; d) the same, but with roller hardening;

## The Selectivity of VHF Broadcast Receivers

shape and form of the linear selectivity characteristic depends on the input level and when this increases the characteristic shifts towards the high-frequency region. The bandwidth measured at the 6 dB level is 320 kc/s and is impermissibly large; the Vesna receiver has similar shortcomings and its bandwidth changes from 325 to 210 kc/s when the input level changes from 25 to 400 microvolts. The performance of the more expensive Druzhba receiver is more satisfactory. The bandwidth changes less because the effect of AGC on input capacitance is less marked, since the grid capacitance of the valve forms a smaller proportion of the total tuning capacitance of the tuned circuits. In West European countries and in the USA a maximum deviation of  $\pm 75$  kc/s is used and even in West German receivers the bandwidth is maintained as low as 120 to 140 kc/s. Several recommendations are made: adjacent channel interference should be considered at 150 kc/s intervals; a better method of selectivity measurement must be devised; circuit design should be

## The Selectivity of VHF Broadcast Receivers

± 250 kc/s from the centre frequency. The selectivity is defined as the ratio of the appropriate input levels. The selectivity measured this way depends both on the characteristics of the IF amplifier and of the FM detector. The real selectivity of the receiver is determined by the ratio of the signal and interference levels at the output of the IF amplifier. A number of measurements have been made on mass-produced receivers of the class II type (Volga and Vesna) and of a higher priced model (Druzhba). Figs 1, 2 and 3 show the linear selectivity (amplitude frequency characteristic of the IF amplifier); characteristics of the FM detector taken from the grid of the preceding valve; the transfer characteristics of the FM detector, taken from the input of the receiver; and the transfer characteristics of the detector (the dependence of output voltage on the frequency of the input signal for a constant high-frequency voltage at the input of the receiver and a fixed frequency deviation). Curve 2 refers to an input of 25 microvolts, curve 3 refers to 100 microvolts and curve 4 to 400 microvolts. It is evident from the curves that in the case of the Volga receiver the

## The Selectivity of VHF Broadcast Receivers

desired programme, while if the programmes are the same interfering stations need only be spaced more than 100 kc/s away. In the Soviet plan the spacings envisaged are respectively 250 and 125 kc/s. However, these figures were arrived at without taking account of tropospheric interference. Since transmitter instability has rendered common channel working impossible even if transmitters are separated by considerable distances, the spacing between channels has been made not 250 kc/s but 25 kc/s and this has increased the danger of interference by distant stations. One result of this re-allocation of frequencies is re-appraisal of the selectivity necessary in VHF receivers. Now the interference may be expected for channels spaced at 125, 150, 175 and 200 kc/s from the wanted station. The method of measuring selectivity must also be examined. The single-signal method consists of the following steps. A receiver is tuned accurately to an incoming signal from the GSS-ChM with  $\pm 15$  kc/s deviation modulated with a frequency of 400 or 1000 c/s, and input level is adjusted to give an output power equal to 10% of the nominal output. The procedure is repeated

**TITLE:** The Selectivity of VHF Broadcast Receivers (K voprosu ob izbiratel'nosti radioveshchatel'nykh priyemnikov v poddiapazone UKV)

**PERIODICAL:** Elektrosvyaz', 1959, Nr 1, pp 38-43 (USSR)

**ABSTRACT:** According to the present plan for broadcast coverage of the Soviet Union, a four-programme scheme is foreseen for the band 66 - 72 Mc/s in the European part of the USSR, and a six-programme system in parts of the most densely populated multi-racial territories using supplementary bands 64.5 - 66 Mc/s and 72 - 73 Mc/s. The first of these supplementary bands can only be used when the two T.V. channels are absent. Rather close spacing of the channels is envisaged with a minimum spacing of 575 kc/s, which should be adequate for present and earlier receivers. Interference must be considered not only from other stations but also by means of tropospheric scattering. For fairly distant ultra-short-wave stations, distant perhaps 600 to 7,000 kilometers, the experiment has shown that a disturbing station with a different programme must be spaced at least 200 kc/s from the

TITLE: A method of treating anodes in Geiger-Müller counters

PERIODICAL: Referativnyy zhurnal, Fizika, no. 11, 1962, 29, abstract 11-3-57kh P  
(Czechosl. pat., cl. 21g, 18/01, no. 99422, April 15, 1961)

TEXT: An early decomposition of hydrocarbons, caused by an exoelectronic emission from the anode, is sometimes observed in Geiger-Müller counters. The emission is caused by a spontaneous formation of an oxide layer on the anode, containing capture levels. To avoid this appearance, it is proposed to coat the anodes of the counters with an oxide layer in advance to allow the layer have its exact stoichiometric composition and an adequate thickness, since a considerable quantity of lattice defects arises on the boundary between the metal and the oxide. The oxidation must be carried out at a high temperature, and the cooling - gradually to maintain the attained state of the lattice. In the case of a tungsten anode, the oxidation is conducted in the air at 500°C for 10 min, and the cooling up to the working temperature is carried out at a rate of 10°C per min. Title : The Geiger-Mueller Counter with Two Concave Windows.

Orig Pub: Jaderna energie, 1958, 4, No 6, 159-161.

Abstract: The construction and technical data about a counter with two windows for the registration of  $\beta$  - radiation are described. In contrast to existing models, in which the anode is supported by a holder disrupting the homogeneity of the field, the anode in the improved counter is reinforced in the glass bushings cemented to the mica windows. The new counter possesses all the basic properties of the usual counters with hydrocarbon suppression

## A Calculating machine for Controlling Arc-Furnace Duty 105-58-5-4/28

diagram the controlling character in the absence and in the presence of the calculating devices is illustrated. The contradiction between the necessity of a quick removal of the produced deviation of power from the nominal value - and the necessity of a relatively slow compensation of the produced deficiency easily can be removed, when the employed electrodynamic controller is characterized by a maximum high-speed effect, whilst the velocity of the transients (determined by the effect of the calculating machine) is tuned in within the demanded limits at the expense of controlling the amplifier factor of the integrating member. The calculating device reacts to all excitations causing a deviation of the power from its given mean value. The practical experience with the calculating machine shows that during melting at  $T = 10$  sec the variation of the real current caused by excitations does not exceed  $\pm 10\%$  of the arc-current mean value. The one-year lasting test operation of the calculating machine showed that during complicated melting processes the machine guarantees an energy supply with an error not exceeding  $2\%$ . By the aid of the

TITLE: A Calculating Machine for Controlling Arc-Furnace Duty  
(Vychislitel'noye ustroystvo dlya upravleniya rezhimom  
dugovoy pechi)

PERIODICAL: Elektrichestvo, 1958, Nr 5, pp. 15-20 (USSR)

ABSTRACT: At first an analysis of the controlling method of the  
electric operation of arc-furnaces according to the  
ratio between amperage and voltage in the phase is given,  
which now is everywhere in use. It is shown that it is  
useful to abandon this method and to change over to the  
controlling method by means of calculating machines. In  
these the power of effective electric energy supplied  
to the furnace is controlled. This method is based on the  
maintainance of the equations (1), (2) and (3). A scheme  
for an electromechanical variant of a calculating machine  
for one of the furnace phases is given. By means of a

Theory and Application of Anti-corrosion (Cont.) SOV/1882

Sciences; Resp. Ed.: N.D. Tomashov, Professor, Doctor of Chemical Sciences; Ed. of Publishing House: A.L. Bankvitser; Tech Ed.: P.S. Kashina.

PURPOSE: The book is intended for chemists, engineers, and metallurgists concerned with the problem of metal corrosion in underground installations.

COVERAGE: The book contains the papers read at the All-Union Conference of the Committee on the Control of Corrosion of the Academy of Sciences, USSR, held in May, 1956. The following scientific and technical problems discussed at the conference received particular attention: 1) theory of metal corrosion underground (N.D. Tomashov and S.I. Kuznetsov); 2) theory, calculation, and practical application of cathodic and anodic protection of underground installations (A.F. Lunev, T.M. Yershov, V.G. Kotik, V.V. Krasnoyarskiy, and A.N. Tsekun); 3) study of the anticorrosive properties and the improved technology in manufacturing and applying protective coatings to subterranean metallic installations (L. Ya. Tsikerman, V.I. Zhukov, M.D. Dzhafarov, and V.S. Artamonov); 4) prevention of stray current corrosion (I.V. Strizhevskiy, J.K. Tomlyanovich, P.G. Doroshenko, and

Experience in Electrically Protecting Main Pipe Lines (Cont.)

has developed a cathode protection installation which is automatically cut out on the appearance of stray currents and with an excessive increase of negative potential on the pipe line. Protection is improved by reducing the longitudinal resistance of the rail network and by increasing the resistance to current spread (drainage, sleeper impregnation, rubble ballast, reducing the amount of grounded metal equipment connected with the rails.

BIBLIOGRAPHY: [Unspecified] eight titles.
